Identifiers- Factor Analysis Of Data Matrices, P Horst

Two factor analysis algorithms, previously described by P. Horst, have been programed for use on the General Electric Time-Sharing Computer System. The first of these, Principal Components Analysis (PCA), uses the Basic Structure Successive Factor Method With Residual Matrices algorithm to obtain the principal component vectors of a correlation matrix. The program will accept up to fifty variables in the correlation matrix and will successively compute up to thirty component vectors; it terminates upon finding a latent root less than one. Varimax Rotation (VARR) uses the Successive Factor Varimax Solution algorithm to produce a normalized rotated factor matrix, given no more than 10 principal component vectors of up to 50 variables. FORTRAN listings and sample runs of both programs are appended. (RM)

Introduction

This note describes two computer programs which are available for factor analysis using the General Electric Time-Sharing Computer System. One program obtains the principal components of a correlation matrix; the other makes an orthogonal transformation of the principal components using a varimax algorithm. The primary purpose of this paper is to facilitate use of the programs; for theoretical interpretations and mathematical detail the reader should refer to the books listed in the bibliography section. With regard to computational aspects, some familiarity with the Time-Sharing Computer System is assumed.

The factor analysis package consists of two completely separate programs named PCA (Principal Components Analysis) and VARR (Varimax Rotation). In most applications the analysis would proceed according to the following sequence: 1. Run PCA, 2. Visually inspect the output of PCA and choose the principal components to be rotated, 3. Run VARR. Either program, however, may be used alone if desired.

The basic input to PCA is the correlation matrix which summarizes the original data. The terminal output includes the principal component vectors, listed in order of the variance accounted for, and the latent roots of the correlation matrix. Some additional output is optionally available. PCA also writes the principal component vectors (referred to collectively as the principal component matrix) in a permanent file named PC (Principal Components) where they may be used later by the program VARR.

The basic input to VARR is a set of principal component vectors. The terminal output includes the rotated factor matrix, the percent of variance which is accounted for by each vector and some additional optional output.

Principal Components Analysis

There are a number of possible procedures for obtaining the principal components of a correlation matrix. The particular algorithm followed by PCA is one which Horst[1/] calls the Basic Structure Successive Factor Method With Residual Matrices. The method is a step-wise procedure which solves for one principal component factor at a time. The effect of a given factor is removed from the correlation matrix leaving a residual matrix from which the next factor is then obtained. PCA continues to extract factors from the residual matrices until a latent root less than one is obtained; the factor associated with that root then becomes the last principal component.

The procedure is iterative with respect to the solution for each principal component. That is, the solution begins with an initial approximation vector and proceeds through successive iterations with each cycle yielding a better approximation to the correct factor. Because

---

1/ P. Horst, Factor Analysis of Data Matrices, (New York: Holt, Rinehart and Winston, 1965, pp. 156-167).

the procedure is iterative, information must be supplied to the program to control termination. The detailed requirements are discussed in the section on input and output.

An exact basic structure solution yields factors which are mutually orthogonal to one another. The iterative method of PCA gives factors which are approximately orthogonal if enough iterations are carried out.

The first principal component obtained by PCA tends to account for the maximum variance which can be accounted for by a single factor. If enough iterations are carried out, each successive factor accounts for the maximum variance not previously accounted for.

Other properties of the solution and an outline of the procedure are given by Horst[2/]. The purely computational parts of the program are almost identical to those provided by Horst[3/]. The dimension and input/output statements have, of course, been changed to conform to Time-Sharing FORTRAN. A listing of the program may be found in Appendix A.

Varimax Rotation

Varimax is the name given to one analytical procedure for making an orthogonal transformation of principal component factors. As a consequence of the varimax rotation the number of large and small loadings

---

2/ Ibid., pp. 157-167.
3/ Ibid., Appendix, p.607.

tend to be maximized and the number of intermediate loadings tend to be minimized. In the foregoing sense the final factor matrix is regarded as a simple structure.

There are several possible variations of the varimax computational procedure. The one used in VARR is referred to by Horst[4/] as the Successive Factor Varimax Solution. The new factor vectors are obtained in a step-wise fashion. The first factor tends to be that one for which the variance of the squared loadings is maximized. Subsequent factors are mutually orthogonal and, subject to this constraint, tend to come out in the order of the variance of their squared loadings.

The procedure followed in VARR is the so-called normal varimax in that each row of the principal components matrix is divided by the corresponding communality. The final varimax rotated matrix is thus normalized. It should be noted, however, that the Successive Factor Varimax Solution does not give the same answer as the varimax method originally suggested by Kaiser[5/].

As in PCA, each vector is obtained by an iterative procedure and information must be supplied to the program to control truncation. Details will be found in the input/output section.

4/ Ibid., pp. 423-428

5/ H.F.Kaiser, "Computer Program for Varimax Rotation in Factor Analysis," Educational and Psychological Measurement, Vol. 19, No. 3, Autum 1959, pp. 413-420.

Restrictions

The principal components analysis will accept up to fifty variables in the correlation matrix and will compute up to thirty principal components. Extraction of principal components is automatically stopped, however, after appearance of the first latent root less than one.

The varimax analysis will accept up to ten principal components with up to fifty variables.

Input and Output

PCA Program

Part of the input to PCA is via a data file named RMAT (R Matrix) and part is entered on-line during execution of the program.

Prior to running PCA, the upper triangle of a correlation matrix is entered in RMAT in Time-Sharing FORTRAN standard input format. The contents of a sample RMAT file are shown in Appendix B. Only the sequence of values is important; the arrangement of data with respect to line numbers is optional.

After the correlation matrix has been entered in RMAT, PCA is ready to RUN. During execution of PCA a request for five more items of information will appear on the teletypewriter in the following form:

```
N,INMAT,IRES,P,LI=
?
```

The user must then enter five numerical values from the keyboard. The symbols have the following meanings.

N — The order of the correlation matrix entered in RMAT.

INMAT — A programming variable which controls the output. If INMAT=1, the correlation matrix is printed as part of the output; if INMAT=0, printing of the correlation matrix is suppressed.

IRES — A programming variable which controls the output. If IRES=1 (and INMAT=1), each residual matrix is printed out; if IRES=0, the residual matrices are not printed. If IRES has a value of one then so must INMAT.

P — A stabilization limit on the number of iterations performed to extract any given principal component. After each iterative cycle a "measure of improvement"[6/] is computed and compared to the value of P.

6/ For a details regarding the "measure of improvement" see the listing of PCA in Appendix A or Horst, op.cit.

When the"measure" is less than the value of P, the iterative procedure is truncated. The user may enter a positive value if he chooses or by entering a zero the program automatically sets P equal to .00001, a value which will probably be satisfactory for most purposes.

LI An absolute limit on the number of iterations performed to extract any given principal component. The user may enter a positive integer if he chooses or by entering a zero the program will automatically set LI equal to 30.

After entering the required data the printout at the teletypewriter might then appear as follows (user supplied information is underlined):

```
N,INMAT,IRES,P,LI=
? 9,1,1,0,0
```

The output of PCA is as follows:

CORRELATION MATRIX.(optional) The lower triangle of the input correlation matrix.

PRINCIPAL COMPONENT i. The i^{th} principal component written as a row vector. The loading on the first variable appears first and so on.

RESIDUAL MATRIX i. (Optional) The residual matrix after the i^{th} principal component has been extracted. Written in lower triangular form.

NUMBER OF ITERATIONS. The number of iterations required to extract each principal component. Written in the order of extraction.

LATENT ROOTS. The latent root associated with each principal component. Written in order of extraction.

CUMULATIVE PERCENT OF VARIANCE ACCOUNTED FOR BY COMPONENTS. The cumulative percent of total data variance which is accounted by the first i components.

See Appendix C for a sample output.

PC Data File

The principal components extracted by PCA are stored in a file called PC for later use as input to VARR. The components are stored in Time-Sharing FORTRAN standard format in the order in which they were extracted, i.e., the first component extracted is first in the file and so on. Contents of a sample PC file may be found in Appendix C.

Prior to running PCA, a dummy PC file must be set up large enough to contain the principal components which are output from PCA. The Time-Sharing Library contains items of six different sizes which

may be used to set up the dummy file.[7]

A set of principal components may also be entered directly into PC rather than as output from PCA.

VARR Program

Part of the input (viz., the principal components) to VARR is from the file PC and part is entered on-line during execution of the program.

A set of principal components must be available in PC prior to running VARR. Procedures pertaining to PC have already been discussed.

During execution of VARR a request for six more items of information will appear on the teletypewriter in the following form:

```
M,N,INMAT,ITRANS,P,NL=
?
```

---

1 General Electric Company, Time-Sharing FORTRAN Reference Manual, (General Electric Company, October 1966, pp. 65-66).

The user must then enter six numerical values from the keyboard. The symbols have the following meanings:

M — The number of principal components to be rotated. The first M principal components in PC will be rotated.

N — The number of variables represented in each principal component.

INMAT — A programming variable which controls the output. If INMAT=1, the M principal components are printed out; if INMAT=0, printing is suppressed.

ITRANS — A programming variable which controls the output. If ITRANS=1, the final transformation matrix is printed out; if ITRANS=0, printing is suppressed.

P — A stabilization limit on the number of iterations performed to obtain any given rotated vector. After each iterative cycle a "measure of improvement" 8/ is computed and compared to the value of P. When the "measure" is less than the value of P, the iterative procedure

---

8/ For details regarding the "measure of improvement" see the listing of VARR in Appendix D or Horst, op.cit.

is truncated. The user may enter a positive value if he chooses or by entering a zero the program automatically sets P equal to .0001, a value which will probably be satisfactory for most purposes.

NL An absolute limit on the number of iterations performed to rotate any given principal component. The user may enter a positive integer if he chooses or by entering a zero the program will automatically set NL equal to 40.

After entering the required data the printout at the teletypewriter might then appear as follows (user supplied information is underlined):

```
M,N,INMAT,ITRANS,P,NL=
? 4,9,1,1,0,0
```

The output of VARR is as follows:

PRINCIPAL COMPONENT MATRIX. (optional). The M principal components selected for rotation. Each component is in column vector form.

NUMBER OF ITERATIONS. The number of iterations required to obtain each rotated factor. Written in order of their transformation.

PERCENT VARIANCE ACCOUNTED FOR BY EACH FACTOR. The percent variance accounted for by each factor with respect to only the variance accounted for by the M principal components. That is, the sum of these percentages add to 100% neglecting round-off error.

FINAL TRANSFORMATION MATRIX. (Optional) The matrix which transforms the principal components matrix to the varimax rotated factor matrix. Written as a series of column vectors.

VARIMAX ROTATED FACTOR MATRIX. The new factors written as column vectors in the order of their transformation.

APPENDIX B

Sample PCA Problem

The sample problem is one given by Horst[9/]. The correlation matrix is:

1.000	.829	.768	.108	.033	.108	.298	.309	.351
	1.000	.775	.115	.061	.125	.323	.347	.369
		1.000	.272	.205	.238	.296	.271	.385
			1.000	.636	.626	.249	.183	.369
				1.000	.709	.138	.091	.254
					1.000	.190	.103	.291
						1.000	.654	.527
							1.000	.541
								1.000

A listing of the input as it appears in the data file RMAT is as follows:

```
110 1.,.829,.768,.108,.033,.108,.298,.309,.351,1.,.775
120 .115,.061,.125,.323,.347,.369,1.000,.272,.205,.238,

APPENDIX E

Sample VARR Problem

The problem for VARR is to rotate the following principal components:

Principal Component 1	Principal Component 2	Principal Component 3	Principal Component 4
.7152	-.4965	-.3478	.0305
.7385	-.4818	-.3190	.0570
.7720	-.3000	-.4048	-.0094
.5574	.6470	-.0710	-.1074
.4654	.7418	-.1844	.1175
.5196	.6912	-.1918	.1312
.6403	-.0784	.5883	.2845
.6145	-.1645	.6222	.1661
.7151	.0335	.3677	-.5648

A listing of this input as it appears in the data file PC is given below.

```
1000     .7152     .7385     .772     .5574     .46
1010     .5196     .6403     .6145    .7151
1020    -.4965    -.4818    -.30      .647      .74
1030     .6912    -.0784    -.1645    .0335
1040    -.3478    -.319     -.4048   -.071     -.18
1050    -.1918     .5883     .6222    .3677
1060     .0305     .057     -.0094   -.1074     .11
1070     .1312     .2845     .1661   -.5643
```

The values for M, N, INMAT, ITRANS, P, NL are 4,9,1,1,0,0, respectively, and are supplied on-line.

APPENDIX F

Sample VARR Output

Printed below is the output from a varimax rotation of the principal components given in Appendix E. Information supplied on-line by the user is underlined.
